

US009368976B2

(12) **United States Patent**  
**Baarman**

(10) **Patent No.:** **US 9,368,976 B2**  
(45) **Date of Patent:** **Jun. 14, 2016**

(54) **ADAPTIVE INDUCTIVE POWER SUPPLY WITH COMMUNICATION**

(71) Applicant: **Access Business Group International LLC, Ada, MI (US)**

(72) Inventor: **David W. Baarman, Fennville, MI (US)**

(73) Assignee: **Access Business Group International LLC, Ada, MI (US)**

(\*) Notice: Subject to any disclaimer, the term of this patent is extended or adjusted under 35 U.S.C. 154(b) by 0 days.

(21) Appl. No.: **14/471,882**

(57) **ABSTRACT**

An adaptive inductive ballast is provided with the capability to communicate with a remote device powered by the ballast. To improve the operation of the ballast, the ballast changes its operating characteristics based upon information received from the remote device. Further, the ballast may provide a path for the remote device to communicate with device other than the adaptive inductive ballast.

### BACKGROUND OF THE INVENTION

This invention relates generally to contactless power supplies, and more specifically to contactless power supplies capable of communicating with any devices receiving power from the contactless power supplies.

Contactless energy transmission systems (CEETS) transfers electrical energy from one device to another without any mechanical connection. Because there is no mechanical connection, CEETS have many advantages over conventional energy systems. They are generally safer because there is little danger of sparks or electric shocks due to the isolation of the power supply. They also tend to have a longer life since there are no contacts to become worn. Due to these advantages, CEETS have been used in everything from toothbrushes to portable telephones to trains.

CEETS are composed of power supplies and remote devices. The remote device could be chargeable devices such as batteries, micro-capacitors, or any other chargeable energy source. Alternatively, CEETS could directly power the remote devices.

One kind of CEETS uses magnetic induction to transfer energy. Energy from a primary winding in the power supply is transferred inductively to a secondary winding in the chargeable device. Because the secondary winding is physically spaced from the primary winding, the inductive coupling occurs through the air.

Without a physical connection between the primary winding and the secondary winding, conventional feedback control is not present. Thus, control of the energy transfer in a CEETS from the primary to the secondary is difficult.

One common solution is to design a CEETS dedicated to one type of device. For example, a CEETS for a rechargeable toothbrush is designed only for recharging a toothbrush, while a CEETS for a rechargeable telephone works only with a specific type of telephone. While this solution allows the CEET to operate effectively with one particular device, it fails to be sufficiently flexible to allow the power supply to operate with different remote devices.

Further, since the remote device could be an electronic device capable of performing various tasks, communication with the remote device is desirable. One such system is described in U.S. Pat. No. 6,597,076, in which an actuator powered by a CEET communicates with a process computer in order to provide information relating to up-to-date actuator information. The remote device communicates with a transceiver located at a central processor. Direct communication between the CEET and the actuator is not, however, provided.

2

In a system shown in U.S. Pat. No. 5,455,466, a portable electronic device receives power from a CEET. Communication between a computer and the portable electronic device is provided by way of the CEET. The CEET acts as a pipeline between the portable electronic device and the computer. The CEET does not obtain information related to the operation of the CEET from the remote device.

While these prior art systems do provide communication, they fail to provide a method or means for the remote device to supply information which could be helpful to the operation of the CEET. For example, a CEET with an adjustable power output could use power requirements from the remote device to operate more efficiently by adjusting its power output. Thus, enabling a CEET to communicate with a remote device in order to obtain power requirements from that remote device is highly desirable.

### SUMMARY OF THE INVENTION

A contactless power supply has a resonant circuit having a variable resonant frequency and a primary winding for transferring power to a remote device. The contactless power supply also may have a receiver for communicating with the remote device. The remote device sends power information to the controller. The controller then modifies the operation of the resonant circuit in response to the power information. Thus, the controller can precisely calibrate the power supply for operation with the remote device, providing high efficiency power transfer from the contactless power supply to the remote device.

The contactless power supply could have an inverter and a power source in addition to the resonant circuit coupled to the inverter. In order to achieve high efficiency power transfer, the controller can modify the rail voltage of the power supply, the frequency of operation of the inverter, the duty cycle of the inverter as well as the resonant frequency of the resonant circuit.

The contactless power supply can also be provided with a memory for storing the power information received from the remote device.

The contactless power supply could also operate with a number of remote devices. The contactless power supply would then receiver power information from each of the remote devices. A list of the power information for each of the remote devices is maintained. Based upon the list, the controller determines an optimal settings for the rail voltage, resonant frequency or the duty cycle based upon the list.

The contactless power supply may also have a communication interface for communicating with a workstation. The controller would create a communication link between the workstation and the remote device by way of a transceiver.

The remote device has a remote device controller and a secondary winding having a secondary winding variable impedance. The remote device controller is capable of varying the secondary winding variable impedance. The remote device has a remote device transceiver for communicating with the contactless power supply. The remote device controller varies the secondary winding variable impedance based upon information from the contactless power supply. The remote device's controller could also disable the operation of the remote device based upon information from the contactless power supply. Thus, the remote device could also be operated at a high efficiency.

Thus, the system allows the optimization of both the power supply as well as the device attached to the power supply.

The contactless power and remote devices operate by each remote device sending power usage information to the con-

troller and then adapting the contactless power supply in response to the power usage information. The adaptation of the contactless power supply includes changing the duty cycle, the inverter frequency, the resonant frequency, or the rail voltage.

The power supply could also determine whether the contactless power supply is capable of supplying power to the plurality of remote devices. If not, some of the remote devices could be turned off.

The contactless power supply, the remote device, and the method of operating the power supply and the remote device result in an extremely efficient and very adaptable method of energizing a variety of devices from the power supply. By continually adapting to the addition or removal of loads to the contactless power supply, the contactless power supply remains highly efficient.

These and other objects, advantages and features of the invention will be more readily understood and appreciated by reference to the detailed description of the drawings.

### BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of an adaptive inductive ballast in accordance with one embodiment of the present invention.

FIG. 2 is a schematic diagram of the resonance-seeking ballast of the attached patent application marked to show changes to incorporate the adaptive inductive ballast of the present invention.

FIG. 3 is a flow chart illustrating operation of the adaptive inductive ballast.

FIG. 4 is a block diagram of an alternative embodiment incorporating RF communications and phase control.

FIG. 5 is a flow chart illustrating operation of the adaptive inductive ballast incorporating communications capability.

FIG. 6 shows a contactless energy transmission system connected to a remote device and a workstation.

FIG. 7 is a block diagram for an adaptive contactless energy transmission system with communications capability.

FIG. 8 is a block diagram of a remote device with communications capability.

FIG. 9 is a flow chart showing the operating of an adaptive contactless energy transmission system.

FIG. 10 is an exemplary list of remote devices powered by a contactless power supply with communications capability.

### DETAILED DESCRIPTION OF THE DRAWINGS

For purposes of disclosure, the present invention is described in connection with a resonance-seeking ballast circuit, and more particularly in connection with the inductive ballast described in U.S. patent application Ser. No. 10/246,155 entitled "Inductively Coupled Ballast Circuit," which is incorporated in its entirety by reference into this application. The present invention is, however, well suited for use with other inductive ballast circuits.

A block diagram showing the general construction of an adaptive inductive ballast 10 in accordance with one embodiment of the present invention is shown in FIG. 1. As illustrated, the adaptive inductive ballast 10 generally includes a microprocessor 12 that controls operation of the circuit, a multi-tap primary 14 for generating a magnetic field, a wave shaper and drive subcircuit 16 that generates the signal applied to the primary 14, a current sense subcircuit 18 that monitors the signal applied to the primary 14 and provides corresponding feedback to the microprocessor 12, a capacitance switch 20 for adjusting the capacitance values in the wave shaper and drive subcircuit 16, and an inductance

switch 22 for adjusting the inductance of the multi-tap primary 14. The microprocessor is a conventional microprocessor widely available from a variety of suppliers.

The capacitance switch 20 generally includes two banks of capacitors and a plurality of switches, such as transistors, that are selectively actuatable by the microprocessor 12 to control the values of the two capacitor banks. The capacitors in each bank can be arranged in series or parallel depending on the desired range and distribution of possible capacitance values. The first bank of capacitors replace capacitor 271. Similarly, the second bank of capacitors replace capacitor 272 of the pre-existing resonance-seeking ballast shown in the attached patent application. In effect, the capacitance switch 20 makes capacitors 271 and 272 from the pre-existing resonance-seeking ballast into variable capacitors, the values of which are controlled by the microprocessor 12. Alternatively, the described capacitance switch 20 can be replaced by other circuitry capable of providing variable capacitance.

The inductance switch 22 generally includes a multi-tap primary 14 and a plurality of switches, such as transistors, that are selectively actual by the microprocessor 12 to control the values of the inductance of the primary 14. The multi-tap primary 14 replaces primary 270 of the pre-existing resonance-seeking ballast. In effect, the inductance switch 22 makes primary 270 from the pre-existing resonance-seeking ballast into a variable inductance coil by varying the number of turns in the primary 14, the value of which is controlled by the microprocessor 12. Alternatively, the described inductance switch 22 can be replaced by other circuitry capable of providing variable inductance.

In general operation, the microprocessor 12 is programmed to receive input from the current sense subcircuit 18, which is indicative of the current applied to the primary 14. The microprocessor 12 is programmed to separately adjust the capacitance switch 20 and the inductance switch 22 to cycle through the range of capacitance values and inductance values available to the circuit. The microprocessor 12 continues to monitor the input from the current sense circuit 18 while adjusting the capacitance and inductance values to determine which values provide optimum current to the primary 14. The microprocessor 12 then locks the adaptive ballast into the optimum settings.

Some of the changes required to adapt the resonance-seeking inductive ballast of the prior patent application into an embodiment of the adaptive inductive ballast circuit 10 are noted in the schematic diagram of FIG. 2.

While the pre-existing resonance-seeking ballast is described in greater detail in U.S. patent application Ser. No. 10/246,155, an overview of the circuit may be helpful to a fuller understanding of this invention. A ballast feedback circuit is connected at point A and a control circuit is connected at point B. Oscillator 144 provides half bridge inverter 148 with an alternating signal by way of drive 146. Half bridge inverter powers tank circuit 150. Current sensing circuit 218 provides feedback to oscillator 144. The feedback circuit, control circuit, oscillator, half bridge inverter, drive and current sensing circuit 218 as well as other supporting circuitry is more fully described in the above referenced patent application.

In FIG. 2, a phase delay could be inserted at E and can be controlled as a delay line. This delay can be used to throttle the phase and control secondary amplitude. At F, switched capacitance can adjust the resonant frequency based on the adjustable primary inductance. Simple transistors can be used to switch in and out capacitance. The capacitance is changed when the primary inductor changes as to match load. At G, primary inductance can be switched to adjust the power

5

required by the secondary circuit. RFID or direct communications can indicate the needed load. With that load information, the control processor can adjust the inductance as needed to provide the power required. The inductance can be switched using transistors and multiple taps from the primary inductor controlled by the microprocessor.

The operating sequence of the adaptive inductive ballast circuit is described in more detail in connection with FIG. 3. In operation, the illustrated system waits until it determines that a load is present before applying power to the primary 14. This will save power and may be done by providing each inductively powered device with a magnet that actuates a reed switch adjacent to the primary. Alternatively, a user-actuated switch (not shown) may be provided so that the user can engage the power supply when an inductively powered device is present. As another alternative, the inductively powered device may be configured to mechanically actuate a switch when it is placed into proximity with the primary to signal its presence. As a further alternative, the switching mechanism can be eliminated and the ballast circuit can provide power to the primary 14 regardless of the presence of a load.

Once the power supply circuit is activated, the circuit adjusts its frequency to optimize the current applied to the primary. After the appropriate operating frequency has been determined at initial capacitance and inductance values, the microprocessor locks the ballast circuit into the operating frequency and then begins to cycle through the range of inductance values available through the multi-tap primary. After each change in inductance value, the microprocessor unlocks the operating frequency and permits the ballast circuit to seek resonance, settling at a frequency that provides optimal current to the primary. The microprocessor continues cycling through the available inductance values until it has determined which value provides optimal current to the primary. In one embodiment, a progressive scanning process is used to determine the appropriate inductance value. This is achieved by starting the scanning process with the lowest inductance value, and sequentially stepping up the inductance value until the change in inductance value results in a reduction in the current applied to the primary. The microprocessor will then step back down one inductance value, where the greatest current was achieved. Alternatively, the scanning process may begin with the highest inductance value, and sequentially step down the inductance value until the change in inductance value results in a reduction in the current applied to the primary. The microprocessor will then step back up one inductance value, where the greatest current was achieved. As another alternative, the microprocessor can step through each inductance value to determine the corresponding current, and after stepping through each value, return to the inductance value that provided the greatest current to the primary.

After the appropriate inductance value is determined, the microprocessor locks the circuit at the determined inductance value and begins to cycle through the capacitance values. In one embodiment, the microprocessor uses a progressive scanning technique to determine the capacitance that provides the primary with the greatest current. The scanning process may progress upwardly from the lowest capacitance value or downwardly from the highest capacitance value, as described above in connection with the scanning process for the inductance value. As an alternative to a progressive scanning process, the microprocessor can step through each capacitance value to determine the corresponding current, and after stepping through each value, return to the capacitance value that provided the greatest current to the primary.

6

In this embodiment, the frequency of the ballast circuit is not permitted to vary once the appropriate inductance value has been determined. The microprocessor can, alternatively, be programmed to permit the ballast circuit to seek resonance after each change in capacitance value.

In an alternative embodiment, the microprocessor may be programmed to provide adjustment of only the capacitance value or only the inductance value of the power supply circuit. In the former alternative, the multi-tap primary can be replaced by a conventional single-tap primary and the inductance switch can be eliminated. In the latter alternative, the capacitor bank can be replaced by a single set of capacitors and the capacitance switch can be eliminated. In another alternative embodiment, the microprocessor can be programmed to adjust the capacitance before adjusting the inductance.

As noted above, the present invention is not limited to use in connection with a resonance-seeking ballast. In other applications, a current sensor may be incorporated into the ballast to provide input to the microprocessor that is representative of the current being applied to the primary. In operation without a resonance-seeking ballast, the microprocessor will separately cycle through the various capacitance and inductance values to determine the values that provide optimum power to the primary.

In a further alternative embodiment, the adaptive inductive ballast 10 may include phase delay circuitry (not shown) that permits the ballast 10 to throttle the phase and control secondary amplitude. The phase delay circuitry may include a delay line or a Digital Signal Processor (DSP) that is connected to the wave shaper and drive circuit 16 following the operational amplifier 210.

A further alternative embodiment of the present invention is described in connection with FIGS. 4-5. In this embodiment, the adaptive inductive ballast 10' and the inductively powered device have the ability to communicate, for example, using conventional RF communications or direct communications.

FIG. 4 is a block diagram showing the general components of the adaptive inductive ballast 10'. The adaptive inductive ballast 10' includes a communication coil (not shown) that is separate from the switched primary inductance and primary coil 22'. The communication coil could be part of the primary. The communication coil is connected to the microprocessor 12', which is programmed to receive the information from the inductively powered device and to effect operation of the adaptive inductive ballast 10' based on that information. The inductively powered device also includes a communication coil that could be separate from or integral with the secondary that receives power from the primary. The inductively powered load and the adaptive inductive power supply 10' communicate using conventional communications techniques and apparatus, for example, using standard communications circuitry and standard communications protocol.

Operation of the adaptive ballast 10' is generally identical to that of ballast 10 described above, except as noted below. A flow chart showing the general steps of operation of the ballast 10' is shown in FIG. 5. Through the use of its communications capability, the inductively powered device can relay load information to the adaptive inductive ballast 10', such as the wattage of the load. The adaptive inductive ballast 10' can use this information in determining the appropriate capacitance and inductance values. More specifically, this information can be used to ensure that the primary of switched primary inductance and primary coil 22' is operating at the correct wattage. If not, the switched primary inductance of switched primary inductance and primary coil 22' and capaci-

tance switch **20'** can be used to adjust the wattage of the primary. This embodiment may, in some applications, provide improved operation over adaptive inductive ballast **10** described above because it does not necessarily drive the primary at its highest possible current value. Instead, this embodiment matches the power output of the primary to the power requirements of the inductively powered device, meaning that it may reduce power and save energy when full power is not required.

The aforementioned system of FIGS. **1-5** is further enhanced and explained with reference to FIGS. **6-9**.

FIG. **6** shows an adaptive contactless energy transmission system incorporating one embodiment of the present invention. Contactless power supply **305** is inductively coupled to remote device **306**. Contactless power supply **305** is also connected to workstation **307**. Network **308** is, in turn, connected to workstation **307**.

In one embodiment, contactless power supply **305** establishes a communication link between workstation **307** and remote device **306**, allowing information to be transmitted to and from remote device **306**. If remote device **306** were a PDA (personal digital assistant), information from the PDA could be exchanged with workstation **307**. For example, a PDA could automatically synchronize a calendar and an address list while the PDA was charging. As another example, if remote device **306** were an MP3 player, then songs could be downloaded to and from the MP3 player while the MP3 player was charging.

FIG. **7** shows a block diagram for an embodiment of an adaptive contactless energy transmission system with communication for communicating with a plurality of remote devices.

The adaptive contactless energy transmission system has contactless power supply **305** and remote device **338**, **340**, **342**.

As is well known, power source **310** is a DC power source providing DC (direct current) power to inverter **312**. Inverter **312** converts the DC power to AC (alternating current) power. Inverter **312** acts as an AC power source supplying the AC power to tank circuit **314**. Tank circuit **314** is a resonant circuit. Tank circuit **314** is inductively coupled to secondary winding **316** of remote device **338**.

The secondary windings of remote devices **338**, **340**, **342** have no core. Dashed line **320** indicates an air gap between remote devices **338**, **340**, **342** and power supply **305**.

Circuit sensor **324** is coupled to the output of tank circuit **314**. Circuit sensor **324** is also coupled to controller **326**. Circuit sensor **324** provides information regarding the operational parameters of the power supply. For example, circuit sensor could be a current sensor and provide information regarding the phase, frequency and amplitude of the current in tank circuit **314**.

Controller **326** could be any one of a multitude of commonly available microcontrollers programmed to perform the functions hereinafter described, such as the Intel 8051 or the Motorola 6811, or any of the many variants of those microcontrollers. Controller **326** could have a ROM (read only memory) and RAM (random access memory) on the chip. Controller **326** could have a series of analog and digital outputs for controlling the various functions within the adaptive inductive power supply.

Controller **326** is connected to memory **327**. Controller **326** is also coupled to drive circuit **328**. Drive circuit **328** regulates the operation of inverter **312**. Drive circuit **328** regulates the frequency and timing of inverter **312**. Controller **326** is also coupled to power source **310**. Controller **326** can manipulate the rail voltage of power source **310**. As is well known, by

altering the rail voltage of power source **310**, the amplitude of the output of inverter **312** is also altered.

Finally, controller **326** is coupled to variable inductor **330** and variable capacitor **332** of tank circuit **314**. Controller **326** can modify the inductance of variable inductor **330** or the capacitance of variable capacitor **332**. By modifying the inductance of variable inductor **330** and the capacitance of variable capacitor **332**, the resonant frequency of tank circuit **314** can be changed.

Tank circuit **314** could have a first resonant frequency and a second resonant frequency. Tank circuit **314** could also have several resonant frequencies. As used herein, the term "resonant frequency" refers to a band of frequencies within which tank circuit **314** will resonate. As is well known, a tank circuit will have a resonant frequency, but will continue to resonate within a range of frequencies. Tank circuit **314** has at least one variable impedance element having a variable impedance. By varying the variable impedance, the resonant frequency of the tank circuit will be varied. The variable impedance element could be variable inductor **330** or variable capacitor **332**, or both.

Variable inductor **330** could be a thyristor controlled variable inductor, a compressible variable inductor, parallel laminated core variable inductor, a series of inductors and switches capable of placing select fixed inductors into tank circuit **314**, or any other controllable variable inductor. Variable capacitor could be a switched capacitor array, a series of fixed capacitors and switches capable of placing select fixed capacitors into tank circuit **314**, or any other controllable variable capacitor.

Tank circuit **314** also includes primary winding **334**. Primary winding **334** and variable inductor **330** are shown separate. Alternatively, primary winding **334** and variable inductor **330** could be combined into a single element. Tank circuit **314** is shown as a series resonant tank circuit. A parallel resonant tank circuit could also be used.

Power supply transceiver **336** is also coupled to controller. Power supply transceiver **336** could be simply a receiver for receiving information rather than a device enabling two-way communication. Power supply transceiver **336** communicates with various remote device **338**, **340**, **342**. Obviously, more or less devices than three could be used with the system.

In this embodiment, contactless power supply **305** also has communication interface **311** for connection to workstation **307**. Communication interface **311** could be any of a number of well known or proprietary interfaces such as USB, firewire, or RS-232. Workstation **307** is connected to network **308**. Network **308** could be a LAN (local area network) or the Internet.

Contactless power supply **305** could also have communication controller **313**. Communication controller **313** manages data input and output through communication interface **311** and power supply transceiver **336**. Communication controller **313** performs necessary control functions such as code conversion, protocol conversion, buffering, data compression, error checking, synchronization and route selection as well as collects management information. Communication controller **313** establishes communication sessions between remote devices **338**, **340**, **342** and workstation **307** or any other devices within network **308**. Communication controller **313** could be a front end processor. Depending upon the capabilities of controller **326**, communication controller **313** could be a software module running within controller **326**.

FIG. **8** shows a block diagram of remote device **338**. Remote device **338** is exemplary of remote devices **340**, **342** as well. Remote device **338** includes load **350**. Load **350**

receives power from variable secondary 353. Load 350 could be a rechargeable battery or any other kind of load.

Variable secondary 353 is preferably coreless, allowing variable secondary 353 to operate over a wider range of frequencies. Variable secondary 353 is shown as a variable inductor, although other types of devices could be used in place of the variable inductor.

Remote device controller 352 controls the inductance of variable secondary 353 and the operation of load 350. For example, remote device controller 352 can alter the inductance of variable secondary 353 or turn on or off load 350. Similar to controller 326, remote device controller 352 could be any one of a multitude of commonly available microcontrollers programmed to perform the functions hereinafter described, such as the Intel 8051 or the Motorola 6811, or any of the many variants of those microcontrollers. Controller 352 could have a ROM (read only memory) and RAM (random access memory) on the chip. Controller 352 could also have a series of analog and digital outputs for controlling the various functions within the adaptive inductive power supply.

Memory 354 contains, among other things, a device ID (identification) number and power information about remote device 338. Power information would include the voltage, current and power consumption information for remote device 338. If load 350 were a rechargeable battery, memory 354 might include discharge rates and charging rates.

Remote device 338 also includes remote transceiver 356. Remote transceiver 356 receives and transmits information to and from power supply transceiver 336. Remote transceiver 356 and power supply transceiver 336 could be linked in a myriad of different ways, such as WIFI, infrared, blue tooth, or cellular. Additionally, the transceivers could communicate by way of additional coils on the primary or secondary. Or, since power is being delivered by power supply 305 to remote devices 338, 340, 342, by any one of many different power line communication systems.

Alternatively, remote transceiver 356 could be simply a wireless transmitter for sending information to transceiver 336. For example, remote transceiver 356 could be an RFID (Radio Frequency Identification) tag.

Processor 357 represents the functional component of remote device 338. For example, if remote device 338 were a digital camera, processor 357 could be a microprocessor within the digital camera. If remote device 338 were an MP3 player, processor 357 could be a digital signal processor or a microprocessor and related circuitry for converting MP3 files into sounds. If remote device 338 were a PDA, then processor 357 would be a microprocessor and related circuitry providing the functionality of a PDA. Processor 357 could access memory 354.

Processor 357 is also coupled to secondary device transceiver 356. Thus, processor 357 could communicate through secondary device transceiver 356 with contactless power supply 305, and thereby could communicate with any other devices connected to power supply 305, such as a workstation.

Due to the presence of communication interface 311, remote device 338 could communicate to workstation 307 or the network 308. In order to enable communication between remote device 338 and workstation 307, controller 326 would establish a communication link to remote device 338 by way of transceiver 336.

FIG. 9 shows the operation of the adaptive contactless energy transmission system with communications capability.

After contactless power supply 305 starts (Step 400), it polls all remote devices by way of transceiver 336. Step 402. Step 402 could be continuous, where advancement to Step

404 occurs only if a remote device is present. Alternatively, the following steps could be performed before polling is repeated, although the operations would be performed with reference to a null set. If any remote device is present, it receives power usage information from the remote device. Step 404.

The power usage information could include actual information regarding voltage, current, and power requirements for remote device 338. Alternatively, power usage information could be simply an ID number for remote device 338. If so, controller 326 would receive the ID number and look up the power requirement for remote device 338 from a table contained in memory 327.

After all devices have been polled and the power information for each device has been received, contactless power supply 305 then determines whether any device is no longer present. If so, then a remote device list is updated. Step 408.

The remote device list maintained by controller 326 is shown in FIG. 10. The remote device list could contain for a device ID, a voltage, a current, and a status for each remote device 338, 340, 342. The device number is assigned by controller 326. The device ID is received from remote devices 338, 340, 342. If two remote devices are the same type, then the device ID could be the same. The voltage and current are the amount of voltage or current required to power the device. The voltage and current could be transmitted discretely by remote devices 338, 340, 342, or they could be obtained by using the device ID as a key to a database of remote devices maintained in memory 327. The status is the current status of the device. For example, the device status could be 'on', 'off', 'charging', etc.

Next, contactless power supply 305 determines whether the status of any device has changed. Step 410. For example, remote device 338 could have a rechargeable battery. When the rechargeable battery is fully charged, remote device 338 would no longer need power. Thus, its status would change from "Charging" to "Off." If the status of the device changes, then the remote device list is updated. Step 412.

Contactless power supply 305 then determines if any devices are present. Step 414. If so, then the remote device list is updated. Step 416. The remote device list is then checked. Step 418. If the list was not updated, the system then polls the devices again, and the process restarts. Step 402.

If the list was updated, then the power usage by the remote devices has changed, and thus the power supplied by contactless power supply 305 must also change. Controller 326 uses the remote device list to determine the power requirements of all the remote devices. It then determines if the system can be reconfigured to adequately power all the devices. Step 420.

If contactless power supply 305 can supply power to all of the remote devices, then controller 326 calculates the settings for inverter frequency, duty cycle, resonant frequency, and rail voltage. Further, controller determines the best setting for the variable impedance of secondary winding 353 of remote devices 338, 340, 342. Step 422. It then sets the inverter frequency, duty cycle, resonant frequency, and rail voltage. Step 424. It also instructs remote devices 338, 340, 342 to set the variable impedance of secondary winding 353 to the desired level. Step 424.

On the other hand, if contactless power supply 305 cannot supply power to all of the remote devices, controller 326 determines the best possible power settings for the entire system. Step 426. It may then instruct one or more of remote devices 338, 340, 342 to turn off or change its power consumption. Controller determines the best setting for the variable impedance of secondary winding 353 of remote devices 338, 340, 342. Step 428. It then sets the inverter frequency,

## 11

duty cycle, resonant frequency, and rail voltage for the system. Step 430. Controller instructs remote devices 338, 340, 342 to set the variable impedance of secondary winding 353 at the desired level. The system then returns to polling the devices, and the process repeats. Step 402.

The above description is of the preferred embodiment. Various alterations and changes can be made without departing from the spirit and broader aspects of the invention as defined in the appended claims, which are to be interpreted in accordance with the principles of patent law including the doctrine of equivalents. Any references to claim elements in the singular, for example, using the articles “a,” “an,” “the,” or “said,” is not to be construed as limiting the element to the singular.

The invention claimed is:

1. A contactless power supply for inductively providing power to a plurality of remote devices, said contactless power supply comprising:

a resonant circuit having a primary for transferring power to the plurality of remote devices by an inductive coupling, said resonant circuit having a variable resonant frequency;

an inverter coupled to said resonant circuit, said inverter configured to drive said resonant circuit at a frequency of operation such that power is transferred inductively from said primary to one or more of the plurality of remote devices; and

a contactless power supply controller coupled to said resonant circuit and said inverter, said contactless power supply controller configured to determine a resonant frequency setting for said resonant circuit to transfer power to the plurality of remote devices.

2. The contactless power supply of claim 1 wherein said contactless power supply controller is configured to adjust said variable resonant frequency of said resonant circuit based on at least one of addition, removal, and status change of one or more of the plurality of remote devices.

3. The contactless power supply of claim 1 further comprising a sensor coupled to said resonant circuit, said sensor configured to monitor an operating parameter of said resonant circuit, and wherein said contactless power supply controller is programmed to determine said resonant frequency setting for said resonant circuit based on an output of said sensor indicative of said operating parameter.

4. The contactless power supply of claim 1 further comprising a communication receiver for receiving information wirelessly from the plurality of remote devices, and wherein said contactless power supply controller is programmed to use said information as a basis for determining said resonant frequency setting for said resonant circuit.

5. The contactless power supply of claim 4 wherein said information received from the plurality of remote devices is indicative of a power requirement associated with each of the plurality of remote devices.

6. The contactless power supply of claim 1 further comprising a power supply having a rail voltage, said power supply configured to supply power at said rail voltage to said inverter.

7. The contactless power supply of claim 6 wherein said contactless power supply controller is configured to adjust at least one of said frequency of operation and said rail voltage.

8. The contactless power supply of claim 1 wherein said contactless power supply controller is configured to continually adapt to changes in said inductive coupling with said primary.

9. The contactless power supply of claim 8 wherein said resonant circuit includes at least one variable impedance ele-

## 12

ment, and wherein said contactless power supply controller is configured to adjust said resonant frequency of said resonant circuit by changing an impedance of said variable impedance element.

10. The contactless power supply of claim 9 wherein said at least one variable impedance element includes a variable capacitance element and a variable inductance element.

11. A method of operating a contactless power supply for transferring power wirelessly to a plurality of remote devices, said method comprising:

determining a resonant frequency setting for a resonant circuit to transfer power wirelessly to the plurality of remote devices;

varying a variable impedance element of the resonant circuit to adjust a resonant frequency of the resonant circuit such that the resonant frequency substantially corresponds to the resonant frequency setting; and  
powering the resonant circuit to transmit power wirelessly to the plurality of remote devices.

12. The method of claim 11 further comprising determining at least one of addition, removal, and status change of one or more of the plurality of remote devices, and varying the variable impedance element based on at least one of the determined addition, the determined removal, and the determined status change of the one or more of the plurality of remote devices.

13. The method of claim 11 further comprising sensing a characteristic of operation of the resonant circuit, and determining the resonant frequency setting based on the sensed characteristic of operation.

14. The method of claim 11 further comprising receiving wirelessly communicated information from the plurality of remote devices, and determining the resonant frequency setting based on the wirelessly communicated information.

15. The method of claim 14 wherein the wirelessly communicated information is indicative of a power requirement associated with each of the plurality of remote devices.

16. The method of claim 11 further comprising dynamically adapting transmission of power by repeating the steps of said determining the resonant frequency setting and said varying the variable impedance element.

17. The method of claim 11 wherein the variable impedance element is at least one of a variable capacitance element and a variable inductance element.

18. A contactless power supply for inductively providing power to a plurality of remote devices, said contactless power supply comprising:

a resonant circuit having at least one of a variable capacitor with a variable capacitance and a variable inductor with a variable inductance, said resonant circuit having a variable resonant frequency that varies based on changes in at least one of said variable inductance and said variable capacitance, said resonant circuit having a primary for transferring power wirelessly to the plurality of remote devices;

an inverter coupled to said resonant circuit, said inverter configured to drive said resonant circuit at a frequency of operation such that power is transferred inductively from said primary to one or more of the plurality of remote devices; and

a wireless power supply controller coupled said inverter, wherein said wireless power supply controller is programmed to vary said variable resonant frequency of said resonant circuit by at least one of (i) varying said capacitance of said variable capacitor of said resonant circuit; and (ii) varying said variable inductance of said variable inductor of said resonant circuit.

**13**

**19.** The contactless power supply of claim **18** further comprising a power supply having a rail voltage, said power supply configured to supply power at said rail voltage to said inverter, wherein said inverter is operated according to a duty cycle to drive said resonant circuit at said frequency of operation, and wherein said wireless power supply controller is programmed to vary at least one of said frequency of operation, said duty cycle, and said rail voltage. 5

**20.** The contactless power supply of claim **18** further comprising a communication receiver for receiving information wirelessly from the plurality of remote devices, and wherein said wireless power supply controller is programmed to use said information as a basis for determining a resonant frequency setting for said variable resonant frequency. 10
